Wireframing: IdolChat

With wireframing, I want to capture the basic functionality of the idea that I am exploring. For the IdolChat idea, it is important to capture some basic ideas of what a user should expect out of it:

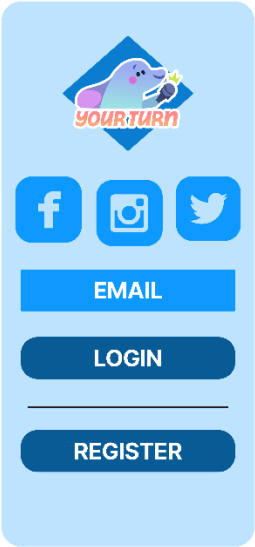
- "With this app, I can chat with a K-Pop idol of my choosing."
- "I should be able to look through a list of K-Pop idols."
- "I expect that the K-Pop idol responds in the way that I expect them to, even if some of the aspects are unexpected."

On the business end, there are some important questions to consider:

- "What will keep the user engaged and coming back to the application?"
- "Who is the target demographic of this application?"
- "How exactly do we monetize this application?"

We will keep some of these questions in mind as we go through this initial wireframe. We won't seek to answer them, but we will seek to be able to wireframe a design that COULD provide answers to them once it goes through more user research and exploration.

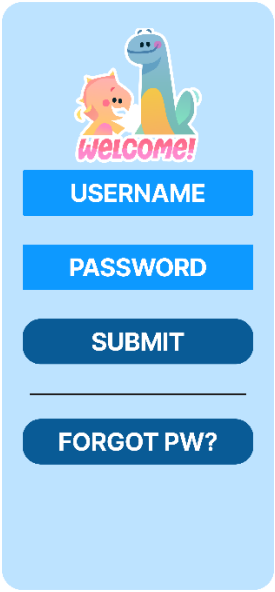
The first step in all of this is to develop a landing page for the application. In this landing page, we would like some sort of logo or image indicating what we are. Additionally, we would like users to be able to utilize either social media logins or email logins (or otherwise register for the application). Our landing page is thus:



The social media and email logins will send the user straight to the relevant sites to verify their login, similar to many other apps. However, we also need a page dedicated to simply having the user register for the application. This page can be simple, as we simply require the user to supply the relevant information for the application. We will ask the user for basic demographic

information, allow them to go back to the landing page (in case they decide they want to use a login method or remember they have an account), a logo to welcome the user, and a submit button to allow them to create an account. This results in the following:

Now, to create a basic login page. Since we'll be asking users to supply us with a specific username and password in order to login, those will be the only necessary fields. Additionally, we will have a button available for those who forget their passwords, which will send them to a form outside of the application to reset it. Also, a cutesy image will be provided, just for the sake of maintaining the cutesy theme.

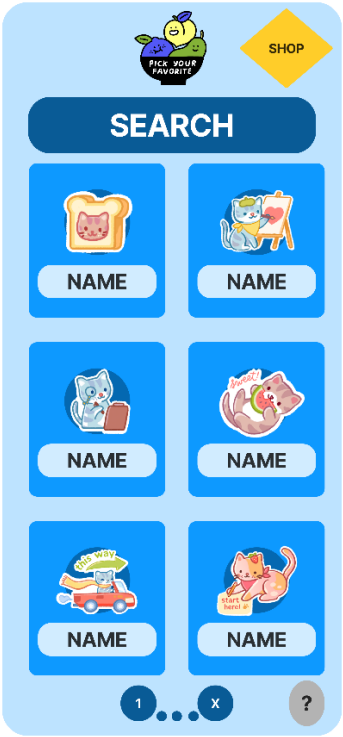


That concludes the basic setup, now we have the user in the application. What happens from here? Do we want to allow the user to just jump straight on in, or do we want to guide the user on how to use the application?

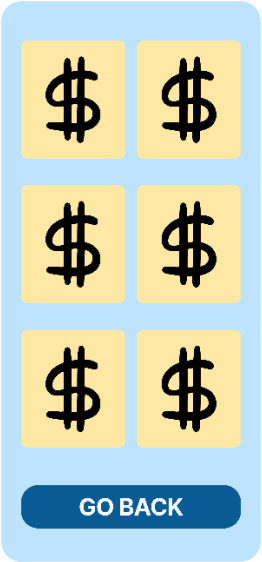
Given that the users of these applications are likely power K-Pop fanatics, they likely already have an idea of which idol they'd like to speak to! This reduces the need to really have to guide the user on the application. Additionally, as the application utilizes a chatbot service, it is simple enough that most users of this demographic are aware of how to use it (functionally, it will be identical to a text message exchange). Therefore, we do not decide to guide the user on how to use the application for the purposes of this wireframing exercise.

Now that we have made this decision, let's go over the features that we want on our main page.

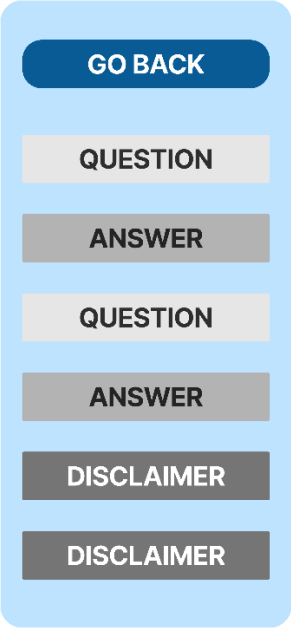
- We want users to be able to search for idols.
- We want to provide boxes containing the idols, including a picture and their name.
    - From here, this will allow the users to select that idol and enter into the chat window.
    - To improve technical performance, it would be ideal if this page worked in a page format.
- We want there to be a button for users to enter our shop, ensuring that we have some form of monetization potential.
- We'll provide a link to a FAQ/Disclaimer page. This page will contain questions that we anticipate for users who may be confused, as well as necessary legal disclaimers.



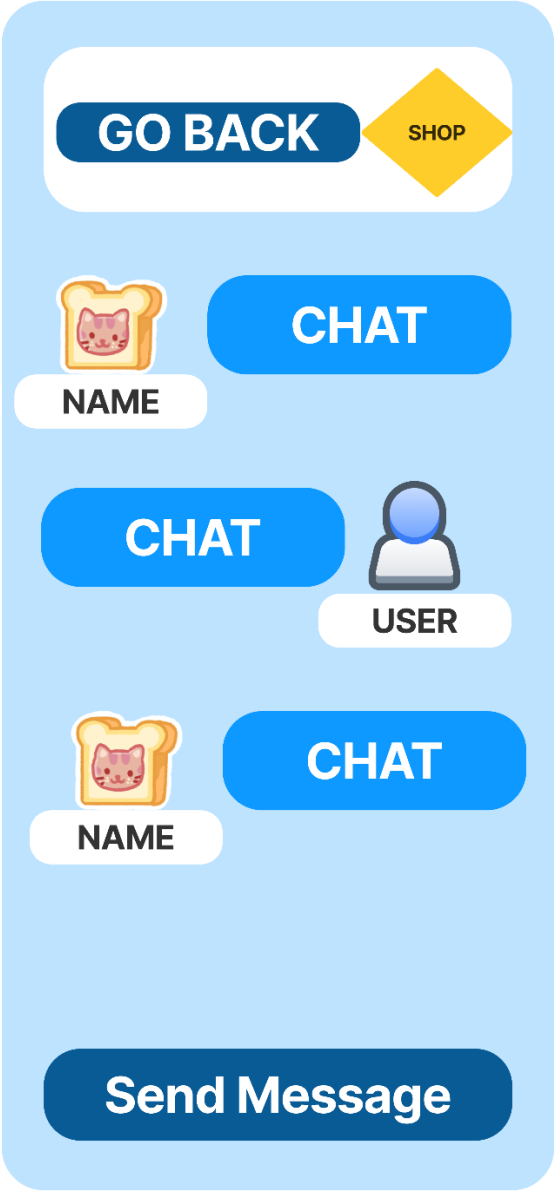
Now, how does our shop screen look like? At the current moment, since pricing has not been determined, we will preliminarily provide the users with six different product options. Additionally, we'll allow the user to go back to their previous page as necessary. We want everything about our shop options to stand out compared to the rest of the app, so we continue to use yellow coloration.



Next, we come down to our FAQ/Disclaimer page. This is a simple list format with all of our relevant questions, answers, and disclaimers. We also allow the user to go back to the previous page.

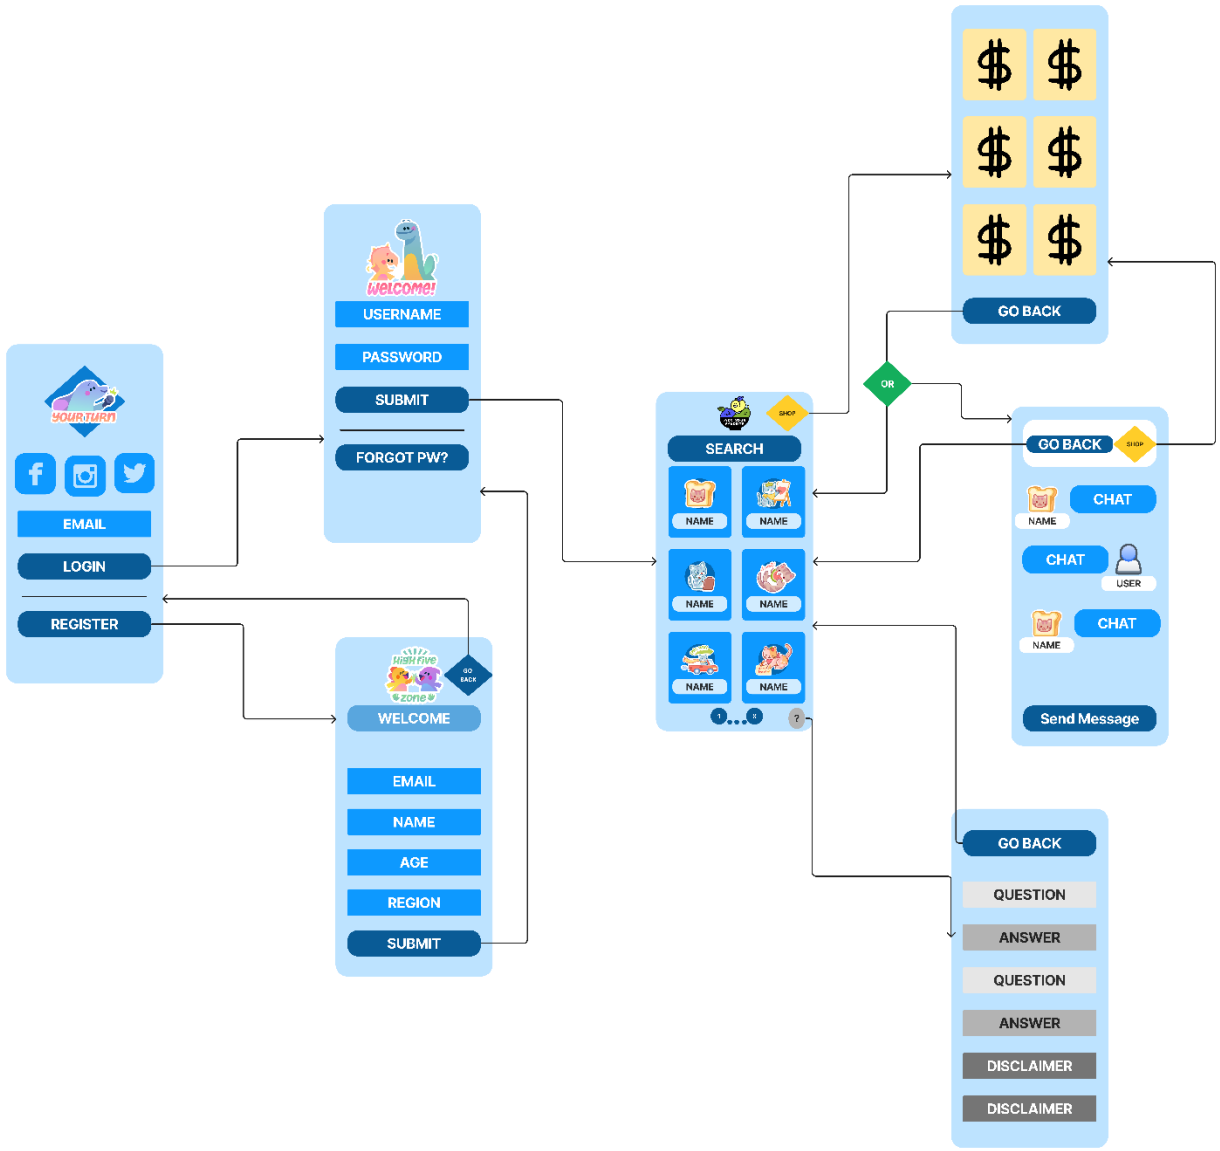


Last but not least, we have to figure out how the actual chatbot application looks like! We want it to look organic and natural, so we'll aim to keep it very similar to a normal text messaging application. Additionally, we'll add an option for a user to return to the main page. The user will undoubtedly wish to chat with their idol of choice, so we provide a field for them to submit their chat message. Finally, we will make sure that the user is aware of the shop, so we add in the shop button here as well.



This concludes the portion of our wireframing where we design the initial wireframes. Now, how exactly do they all come together?

With all of our basic wireframes put together, let's diagram them to make everything who looks at it knows where each button goes.



This concludes the initial wireframing for our IdolChat App idea! Ideally with this, a product manager would utilize it to collaborate with a designer in order to further develop the idea. Other parties may also become involved, but it is recommended to reduce how many individuals are involved in order to reduce an issue of "too many cooks in the kitchen".
